Upper DHGP @ 1531' mTVBDF

(Failed)
Calculated by ODSI
and compared to
historic data

558 mTVD

Lower DHGP @ 2089' mTVDBDF

(Failed)
Calculated by ODSI
and compared to
historic data

800 mTVD

MOC @ 2889' mTVDBDF

Calculated by ODSI
for PTA purposes

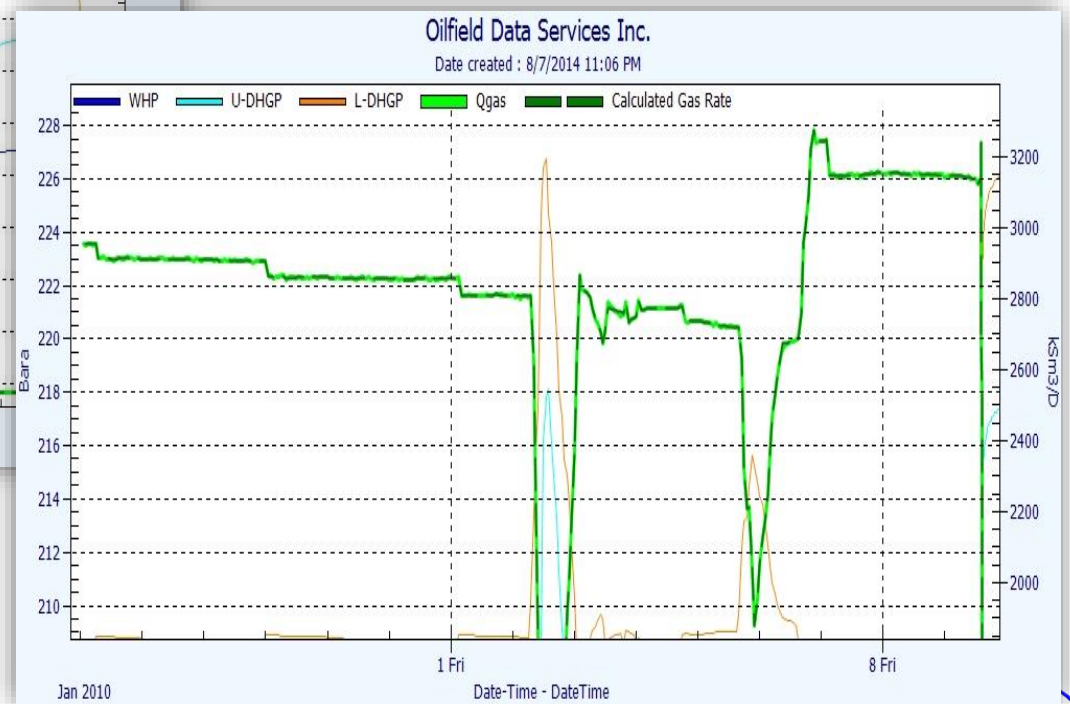

- The well was equipped with multiple gauges
 - Tree gauges
 - Upper downhole gauge (*failed, historic data only*)
 - Lower downhole gauge (*failed, historic data only*)
- The rates were being measured
- Both downhole gauges failed; ODSI performed BHP conversion from the surface data at the Upper and Lower downhole gauge depths & compared the results to historic data when both gauges were functional (**Proof of Concept**)
- ODSI to calculate BHP at the mid-completion depth
- ODSI to perform PTA and evaluate if the well's a stimulation candidate

Data Processing & Results

- PVT and frictional component were calibrated using shut-in data and flowing pressure data (DP wellbore)
- Tree gauge and lower DHGP data used to calculate/validate production rates
- Good MPFM measurements (less than 1% deviation)
- Tree gauge data and calculated rates used to perform BHP conversion at the following depths for proof of concept & PTA purposes:
 - Upper Downhole Gauge
 - Lower Downhole Gauge
 - Mid-completion BHP
- **Note:** All calculations were based on ODSI's direct solution to Mechanical Energy Balance Equation

Results – Rate Comparison

- The gas rate was calculated to demonstrate the accuracy of ODSI's rate calculation method and as a proof of concept
 - Using the DP Wellbore (DP between the Lower DHGP and tree gauge)
 - **Less than 1 % error**

Results – Rate Comparison Zoom

Oilfield Data Services Inc.

Date created : 8/7/2014 11:06 PM

The calculated rates were within 1 % when compared to the metered rates

- The gas rates were calculated using the pressure drop in the wellbore
- When compared to the metered gas rate, the measured rate was within 1 %
- **The method can be used independently:**
 - To validate allocations/MPFM accuracy
 - To determine the onset of the water production
 - PVT tuning
 - Alternative solution if flow meter fails
 - Low-cost investment
 - Does not require additional instrumentation

- BHP was calculated at the Lower & Upper downhole gauge depths to demonstrate the ability to perform accurate pressure conversions at any point along the wellbore
 - Can be used as an alternative solution if DHGP fails
 - Using tree gauge data and the calculated gas rates
- Similarly, Datum P was calculated at the mid-perforation depth

Note: All rate and wellbore calculations were based on ODSI's proprietary solution to *Bernoulli equation*

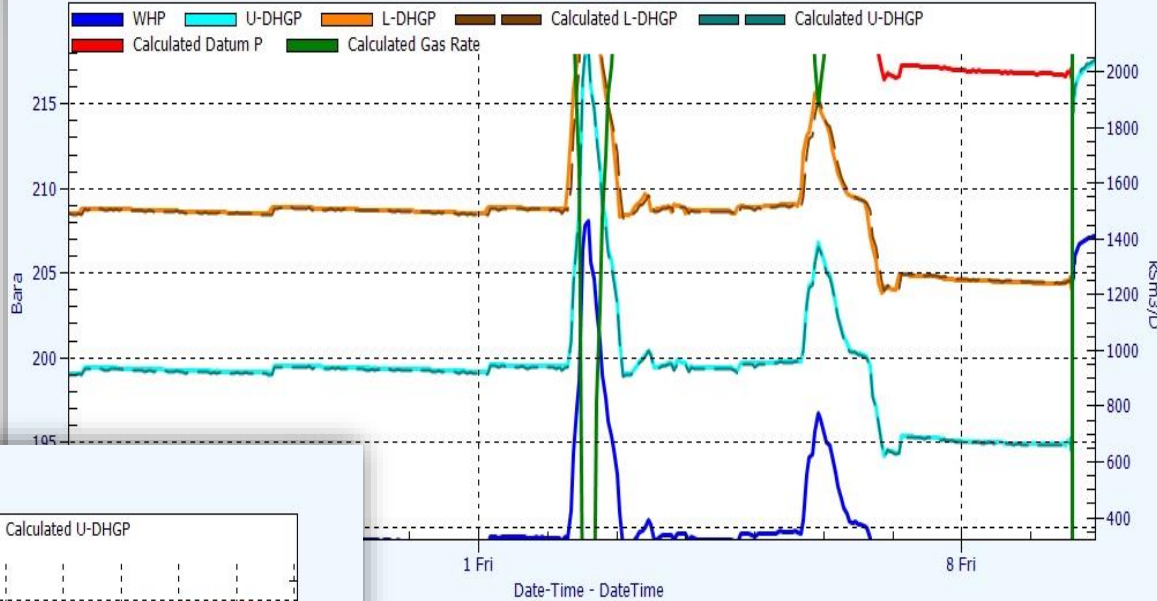

- BHP was calculated at the Lower & Upper downhole gauge depths to demonstrate the ability to perform accurate pressure conversions at any point along the wellbore
 - Can be used as an alternative solution if DHGP fails
 - Using tree gauge data and the calculated gas rates
- Similarly, Datum P was calculated at the mid-perforation depth

- Comparison of the measured vs calculated pressure at the Upper DHGP depth
 - ~ 0.15 bar (0.07 % error)

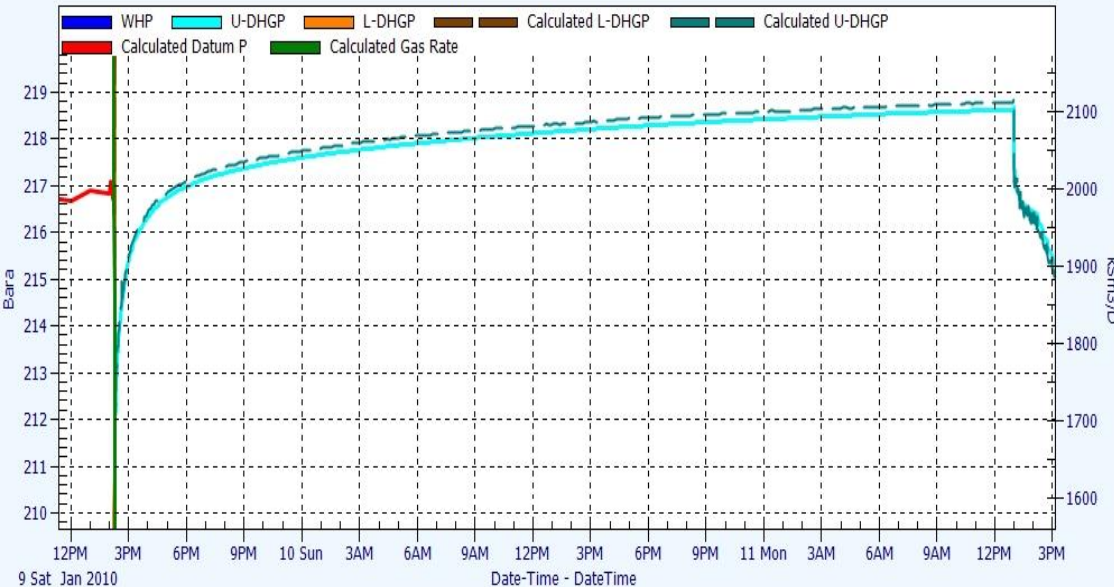

Oilfield Data Services Inc.

Date created : 8/7/2014 11:06 PM

Oilfield Data Services Inc.

Date created : 8/7/2014 11:06 PM

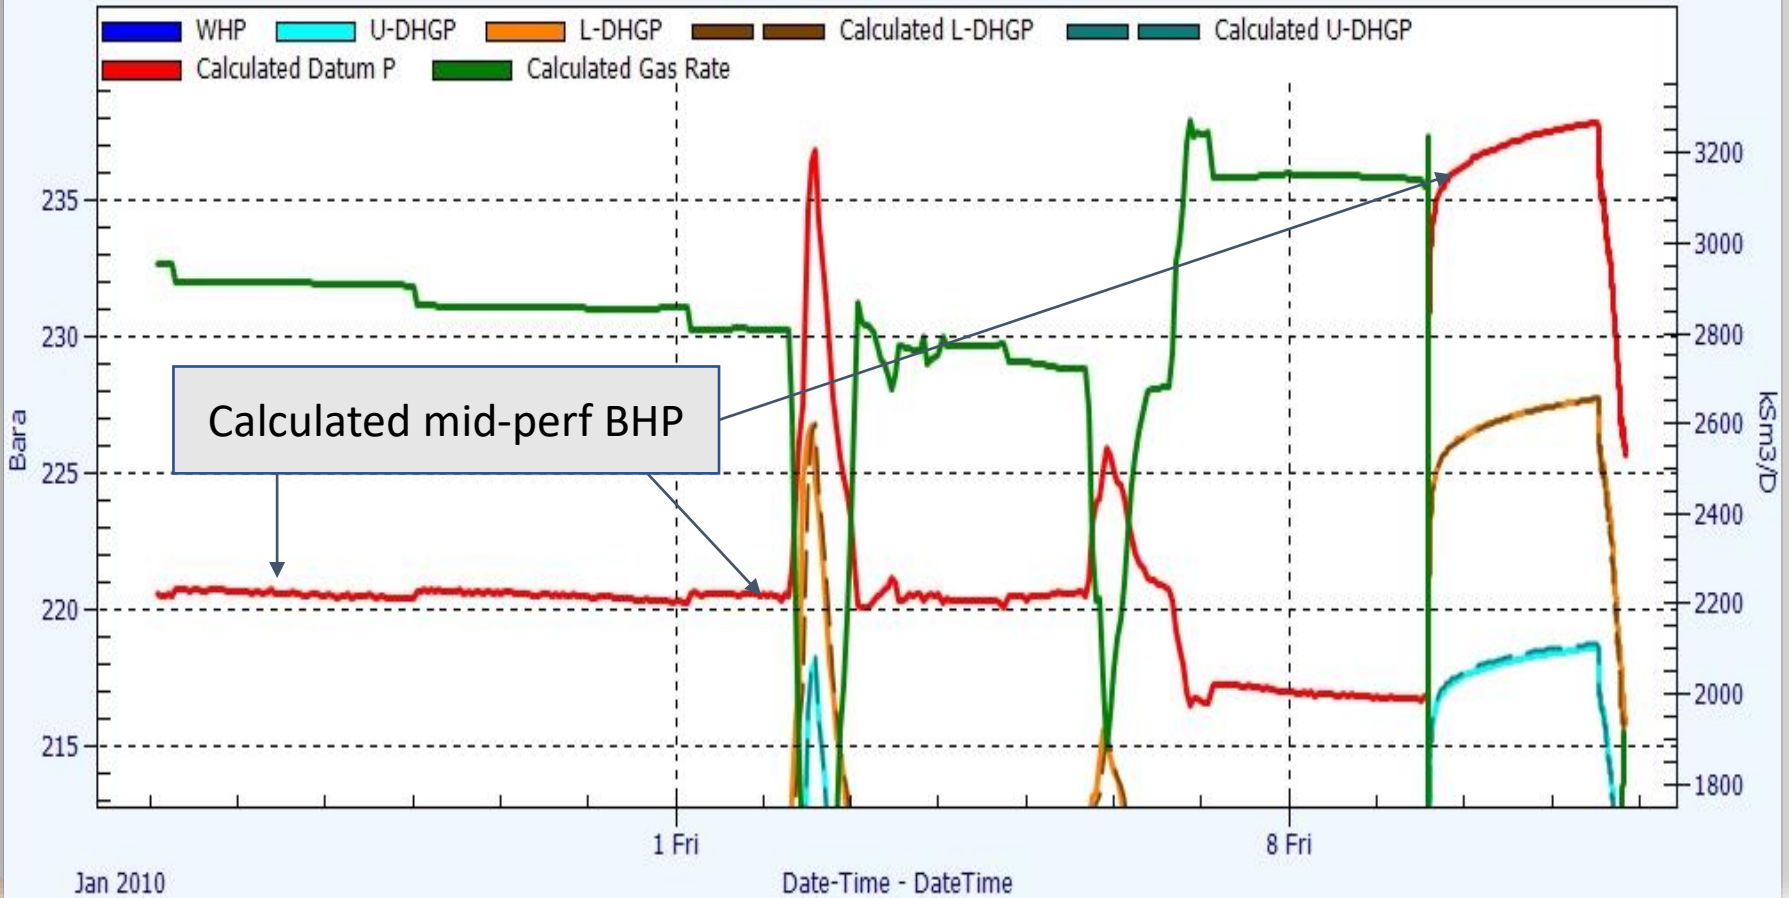

- Comparison of the measured vs calculated pressure at the Lower DHGP depth
 - ~ **0.02 bar (0.009 % error)**

Results: BHP at Datum (mid-perf) Depth

Oilfield Data Services Inc.

Date created : 8/7/2014 11:06 PM

Datum Pressure was calculated at the mid-perforation depth

- Pressure was calculated at the Upper and the Lower DHGP depths to show ODSI's ability to accurately calculate pressure at any point along the wellbore
 - **Within ~ 0.07 % accuracy for the Upper – DHGP**
 - **Within ~ 0.009 % accuracy for the Lower – DHGP**
- Datum P was calculated at the mid-perforation depth

Alternative solution if no downhole gauges are present or downhole gauge fails

PTA Results

- The main objective was to determine if the well was a stimulation candidate
- It was thought that the well had high skin/damage
- Therefore, PTA was performed on
 - WHP
 - Upper DHGP
 - Lower DHGP
 - Datum P/mid-perf BHP

- It is important to use a valid mid-perforation BHP for the PTA purposes
- **Failure to do so leads to:**
 - Overestimation of Skin
 - Overestimation of Permeability
 - Underestimation of Reservoir pressure

(Due to additional friction and fluid density changes below the gauge)

- ODSI's solution accounts for both frictional and phase-thermal changes in the wellbore

Oilfield Data Services Inc.

Date created : 2/7/2017 4:15 PM

Note: The mid-time slope value differences were caused by the wellbore cooling effect during S/I

PTA was performed on the WHP, Upper DHGP, Lower DHGP and the Calculated mid-perf BHP

Failure to use valid BHP leads to overestimation of skin & perm and underestimation of reservoir pressure!

- When the PTA was performed on WHP, the well appeared to have a high skin/damage
- In reality, the well did not have skin
 - Low skin ~ 3.6
 - High permeability ~ 154 md
- **Stimulation of that well would not lead to an improved performance**

Well Analyzer – Rate Calculation Feature

- Accurate rate calculations
 - Matched the metered rate with less than 0.04 % error
- Metered rate validation/MPFM Calibration
- Detects errors in allocations
- Detects changes in fluid composition
- Detects onset of the water production
- Alternative and cost-effective solution if flow meter fails

Well Analyzer – BHP Calculation Feature

- ODSI was able to successfully calculate pressure at the Upper & Lower DHGP depths and match accurately the gauge response
 - Less than 0.07 % error
- Allows accurate BHP conversions from the surface data
- Alternative and cost-effective solution if downhole gauge fails
